

GHOST-MASTER TERMINAL

Complete Production Blueprint: AI Prompts & Native Android APK Export Guide

To turn your Lovable / Supabase / MT5 trading dashboard into a downloadable Android **.apk**, use a two-tier approach: prepare the web assets for native wrapping, then compile via a cloud or local builder (Capacitor / Cordova / Flutter Webview).

Architecture Concept: Treat the Lovable project as a production PWA/SPA and bundle the compiled static assets into a native wrapper to gain native capabilities like push, wake locks, and native distribution.

Phase 1: Production Build Master Prompt (run inside Lovable)

Before compiling, run accessibility and mobile-optimization passes: touch target sizing, viewport rules, offline fallbacks, and asset packaging readiness.

```
Act as a Lead Mobile PWA Architect. Freeze code for an Android APK export and ensure:

1. TOUCH & VIEWPORT OPTIMIZATION: Ensure all actionable controls are >=48px target. Replace scrollbars with native momentum scrolling and disable double-tap zoom.

2. ASSET PACKAGING: Produce a single static output folder (/dist or /build) with relative paths and bundled SVG assets.

3. OFFLINE STANDBY: Provide cached metrics and block order execution while offline; show a clear reconnect modal.
```

Phase 2: Android APK Compilation Blueprint

Choose a compilation method:

Method	Required	Best Suited For	Build Speed
Cloud Build	Git + VoltBuilder / CodeMagic	No local Android Studio	3-5 min
Local Capacitor	Node.js + Android Studio	Full native control	~10 min

Method A: Cloud Compilation (prompt for cloud builder)

```
Generate a production config.xml / voltbuilder.json with:
- package: com.ghostmaster.terminal.app
```

```
- name: Ghost-Master Terminal
- version: 1.0.0
- orientation: portrait
- permissions: network, wake-lock, notifications
Bundle /dist and zip for the cloud compiler.
```

Deployment Note: Upload the /dist zip to VoltBuilder/CodeMagic to receive an APK.

Method B: Local CLI (Capacitor)

Bash script outline:

1. `npm install @capacitor/core @capacitor/cli`
2. `configure capacitor.config.json (webDir -> /dist)`
3. `npx cap add android`
4. `npx cap open android (then Build -> Build APK(s))`

Phase 3: Installation Verification

- **Enable Install Unknown Apps** on the Android device.
- **Bypass Play Protect** if necessary (Install Anyway).
- **Verify Wake Lock** by running the engine for 15 minutes and confirming live metric sync.
